JUNCTIONAL ADHESION MOLECULE (JAM), A TRANSMEMBRANE PROTEIN OF TIGHT JUNCTIONS

The present invention relates to a transmembrane component of tight junction, more
5 precisely a new protein, which is expressed in endothelial cells, epithelial cells,
megakaryocytic cells and platelets. This new protein is now denominated junctional
adhesion molecule (JAM), and most of the human and the whole of the mouse JAM
have been sequenced. The invention further comprises a cDNA coding for JAM, a
structural gene coding for JAM, a recombinant protein or peptide expressed by the
10 structural gene or by a fragment of the gene, an antibody specific for JAM, a
modifier of the polymerization of transmembrane JAM, a diagnostic kit comprising
the antibody or the modifier, a vaccine adjuvant comprising the modifier, a
medicament comprising the modifier, and transgenic animals or cells
overexpressing or lacking JAM. An example of the modifier is a monoclonal
15 antibody specifically binding to JAM and preventing the polymerization of JAM at
tight junctions, resulting inter alia in the blocking of leukocyte transmigration.

Background

20 The endothelium forms the main barrier to the passage of macromolecules and
circulating cells from blood to tissues. Endothelial permeability is in large part
regulated by intercellular junctions. These are complex structures formed by
transmembrane adhesive molecules linked to a network of cytoplasmic/cytoskeletal
proteins. At least four different types of endothelial junctions have been described:
25 tight junctions, gap junctions, adherence junctions and syndesmos (Dejana et al.,
infra).

Intercellular tight junctions are responsible for the control of endothelial and
epithelial cell layer permeability [Anderson et al; Curr. Opin. Cell. Biol. 5, 772-778
30 (1993)]. These organelles also regulate leukocyte transmigration, cell polarity and
growth. The molecules which constitute the tight junctions are therefore good
targets for developing drugs which affect inflammatory reaction, angiogenesis and
cell proliferation in general [Dejana et al., FASEB J. 9, 910-918 (1995)].

Leukocyte transmigration through the endothelium or the epithelium in inflammation is associated with edema and tissue damage. To transmigrate leukocytes have to open the tight junctions and go through cell-cell contacts [Carlos and Harlan, Blood 84, 2068-2101 (1994)]. Tools which are able to specifically limit this process have not been disclosed in the prior art.

Tumor cells seem to use similar mechanisms to transmigrate through the endothelium and infiltrate tissues. Agents which could prevent tight junction opening would be therefore useful in limiting tumor metastasis.

In addition, tight junctions are particularly important in the brain microvasculature where they are responsible for a tight control of permeability between the blood and the central nervous system [Risau and Wolburg, Trends Neurosci. 13, 174-178 (1990)]. This endothelial barrier constitutes a strong obstacle to the access of useful drugs to the brain as for instance the penetration of chemotherapeutics for the cure of cerebral tumors. Methods to open or to repair the blood brain barrier without induction of endothelial damage have not yet been described in the literature.

Finally, the tight junctions are poorly expressed in epithelial cell derived tumors, and some tight junction components have oncosuppressor activity, i.e., their presence reduces the capacity of the tumor to proliferate and to metastasize [Tsukita et al., J. Cell Biol. 123, 1049-1053 (1993)]. Transfection of the tight junction molecule genes could be seen as a way to limit tumor progression. In addition, since tight junctions are needed for a correct organization of new vessels, inhibition of their organization might prevent angiogenesis and thus inhibit the development of proliferative diseases such as cancer.

The molecular organization of tight junctions is so far only partially characterized. Only one transmembrane protein which is specific for tight junctions has been identified and denominated occludin [Furuse et al., J. Cell Biol. 123, 1777-1788 (1993)]. This protein connects specific cytoskeletal proteins inside the cells. The adhesive properties of occludin and its capacity to promote homotypic cell-to-cell interaction are not conclusively proven yet.

Description of the invention

The present invention is based on the finding of a new transmembrane protein located at tight junction. This new protein is called junctional adhesion molecule and is abbreviated JAM. This JAM protein, located at tight junctions, promotes cell-to-cell homotypic adhesion. The extracellular parts of the proteins adhere to each other on the same and adjacent cells by protein dimerization, oligomerization or polymerization in a zipper-like fashion and causes a strong reduction in paracellular permeability.

The JAM used in the experimental part of this specification is of mouse origin, whereas the JAM of human origin is the one which will be predominantly used as a model for the development of diagnostics and medicaments for use in, e.g., tumor therapy, angiogenesis control, control of Blood Brain Barrier, control of inflammatory response, control of transmigration of leukocytes, control of transmigration of other natural or engineered cells such as gene therapy in the brain.

Thus, the first aspect of the invention is directed to a protein in glycosylated or unglycosylated form comprising an amino-acid sequence selected from the sequence SEQ ID NO:1

and homologous sequences having at least 72 % homology to the sequence SEQ
 ID NO: 1. The percentage of homology may for instance be 75%, 80% or as high as
 85 %, or even higher, such as 90 % or 95 %, especially if the homologous
 40 sequence originates from a transmembrane protein of the same or closely related
 species. However, it is anticipated that proteins which have at least 72 % homology
 to this N-terminal sequence SEQ ID NO: 1 (some amino-acid residues at the C-
 terminal are missing from the full length protein) will share both diagnostic and
 medical properties to such a high degree that they can be used for the various
 45 applications of the present invention. Among such proteins may be included both

naturally occurring analogues and variants of the same or different species as well as synthetic or recombinant equivalents. An example of such a protein having at least 75 % homology to the SEQ ID: 1 is the mouse JAM protein having the amino-acid sequence SEQ ID NO: 2

The synthetically or recombinantly produced proteins of the invention will function as competitors at tight junctions.

20 The second aspect of the invention is directed to a DNA sequence coding for a protein of the present invention, specifically a cDNA sequence coding for a protein of the present invention. Specific embodiments of this aspect of the invention are the cDNA sequence SEQ ID NO: 3 (part of human)

55 coding for the protein having the amino-acid sequence SEQ ID NO:2.

The cDNA molecules will find their application in gene therapy, and they can be used as an oncosuppressor by transfection in carcinoma cells lacking this molecule.

- 5 The third aspect of the invention is directed to a gene coding for a protein of the present invention or a peptide derived from the protein. The gene will be used in the production of a protein or peptide of the invention. The flanking regions, such as promoter or leader sequences, are preferably chosen with regard to the expression system to be used to promote good production. Further, the codons
- 10 used in the gene may be selected with regard to the codons most frequently used by the selected expression host, in order to optimize the expression yield. For instance, if yeast is selected as the expression host, the codons may be optimized for yeast. The specific examples of genes of the invention are the protein coding regions of the exemplified cDNAs of the invention, namely the gene having the
- 15 partial nucleotide sequence

coding for the protein having the amino-acid sequence SEQ ID NO:2.

The proteins of the present invention can be chemically synthesized using standard methods known in the art, preferably solid state methods, such as the methods of Merrifield (J. Am. Chem. Soc. 85, 2149-2154 [1963]). Alternatively, the proteins of the present invention can be produced using methods of DNA recombinant technology (Sambrook et al. in "Molecular Cloning - A Laboratory Manual", 2nd. ed., Cold Spring Harbor Laboratory [1989]). Thus the fourth aspect of the invention is directed to a recombinant protein or peptide expressed by a structural gene or a fragment of the gene according to the present invention.

Preferably, DNA coding for a protein of the present invention is isolated through expression cloning. A cDNA expression library is constructed from a murine brain EC line (bEnd.3) as previously described (Fawcett et al., Nature 360, 481 [1992]). COS cells are transiently transfected with the cDNA library, stained in suspension with anti JAM antibody and then panned on plastic dishes coated with the appropriate second antibody.

A DNA sequence coding for a protein of the present invention is incorporated into a suitable expression vector which produces the requisite expression signals.

5 Expression vectors suitable for use in prokaryotic host cells are mentioned, for example, in the aforementioned textbook of Maniatis et al. Such prokaryotic expression vectors which contain the DNA sequences coding for the proteins of the present invention operatively linked with an expression control sequence can be incorporated using conventional methods into any suitable prokaryotic cell. The selection of a suitable prokaryotic cell is determined by different factors which are
10 well-known in the art. Thus, for example, compatibility with the chosen vector, toxicity of the expression product, expression characteristics, necessary biological safety precautions and costs play a role and a compromise between all of these factors must be found.

Suitable prokaryotic organisms include gram-negative and gram-positive bacteria,
15 for example, *E. coli* and *B. subtilis* strains. Examples of prokaryotic organisms are *E. coli* strain M15, described as strain OZ 291 by Villarejo et al. in *J. Bacteriol.* 120, 466-474 (1974) and *E. coli* W3110 (ATCC No. 27325). In addition to the aforementioned *E. coli* strains, however, other generally accessible *E. coli* strains such as *E. coli* 294 (ATCC No. 31446) and *E. coli* RR1 (ATCC No. 31343) can also
20 be used.

Expression vectors suitable for use in mammalian cells include but are not limited to pBC12MI [ATCC 67109], pSV2dhfr [ATCC 37146], pSVL [Pharmacia, Uppsala, Sweden], pRSVcat [ATCC 37152] and pMSG [Pharmacia, Uppsala]. A preferred vector for the expression of the proteins of the present invention is pECE.
25

Mammalian host cells that could be used include, e.g., human Hela, H9 and Jurkat cells, mouse NIH3T3 and C127 cells, CV1 African green monkey kidney cells, quail QC1-3 cells, Chinese hamster ovary (CHO) cells, mouse L cells and the COS cell lines. The CHO cell line (ATCC CCL 61) is preferred.
30

The manner in which the expression of the proteins of the present invention is carried out depends on the chosen expression vector/host cell system.

Usually, the prokaryotic host organisms which contain a desired expression vector
35 are grown under conditions which are optimal for the growth of the prokaryotic host

organisms. At the end of the exponential growth, when the increase in cell number per unit time decreases, the expression of the desired protein is induced. The induction can be carried out by adding an inducer or a derepressor to the growth medium or by altering a physical parameter.

5

The mammalian host cells which contain a desired expression vector are grown under conditions which are optimal for the growth of the mammalian host cells. A typical expression vector contains the promoter element, which mediates the transcription of mRNA, the protein coding sequence, and the signals required for efficient termination and polyadenylation of the transcript. Additional elements may include enhancers and intervening sequences bounded by spliced donor and acceptor sites.

10

Most of the vectors used for the transient expression of a given coding sequence carry the SV40 origin of replication, which allows them to replicate to high copy numbers in cells (e.g. COS cells) that constitutively express the T antigen required to initiate viral DNA synthesis. Transient expression is not limited to COS cells. Any mammalian cell line that can be transfected can be utilized for this purpose. Elements that control a high efficient transcription include the early or the late promoters from SV40 and the the long terminal repeats (LTRs) from retroviruses, e.g. RSV, HIV, HTLV. However, also cellular signals can be used (e.g. human- β -actin-promoter).

15

20

Alternatively, stable cell lines carrying a gene of interest integrated into the chromosome can be selected upon co-transfection with a selectable marker such as gpt, dhfr, neomycin or hygromycin.

25

Now, the transfected gene can be amplified to express large quantities of a foreign protein. The dihydrofolate reductase (DHFR) is a useful marker to develop lines of cells carrying more than 1000 copies of the gene of interest. The mammalian cells are grown in increasing amounts of methotrexate. Subsequently, when the methotrexate is withdrawn, cell lines contain the amplified gene integrated into the chromosome.

30

The baculovirus-insect cell vector system can also be used for the production of the proteins of the present invention (for review see Luclow and Summers, Bio/Techno-

35

logy 6, 47-55 [1988]). The proteins produced in insect cells infected with recombinant baculovirus can undergo post-translational processing including N-glycosylation (Smith et al., Proc. Nat. Acad. Sci. USA 82, 8404-8408) and O-glycosylation (Thomsen et al., 12. International Herpesvirus Workshop, University of Philadelphia, Pennsylvania).

The proteins of the present invention can be purified from the cell mass or the culture supernatants according to methods of protein chemistry which are known in the art such as, for example, precipitation, e.g., with ammonium sulfate, dialysis, ultrafiltration, gelfiltration, ion-exchange chromatography, SDS-PAGE, isoelectric focusing, affinity chromatography like immunoaffinity chromatography, HPLC on normal or reverse systems or the like.

The fifth aspect of the invention is directed to an antibody binding specifically to a protein according to the present invention or a part of the protein. The antibody may be polyclonal or monoclonal. In the experimental part of this specification the preparation of monoclonal antibodies of the invention is disclosed. One of the monoclonal antibodies of the invention mAb BV 12 binds specifically to JAM but does not inhibit transmigration of leukocytes through tight junctions, whereas another monoclonal antibody of the invention mAb BV 11 not only binds specifically to JAM but also inhibits the transmigration of leukocytes through tight junctions. Both types of antibodies binding specifically to JAM may be used in diagnostics, and in diagnostic kits, e.g., for screening or detection of cell damage, particularly by detection of circulating JAM as a marker of early endothelial cell damage.

The sixth aspect of the invention is directed to a modifier of the polymerization of a transmembrane protein according to the present invention.

The term "modifier" is to be interpreted broadly and to comprise in the present specification and appended claims, both inhibitors and activators of the polymerization of the JAM protein of the invention. Thus, the modifiers of the invention will either prevent or promote polymerization of JAM molecules at tight junctions, i.e., the dimerization, oligomerization or polymerization of JAM, or dedimerization, deoligomerization or depolymerization of JAM, respectively, at tight junctions.

The modifier of the invention may be any ligand to the protein of the invention which binds to the protein and has the ability to prevent or promote the polymerization of the protein (JAM). For example, the modifier of the invention may have a structure which is complementary to the protein of the invention or a part of the protein.

5 However, in a preferred embodiment of this aspect of the invention the modifier is selected from the group consisting of polyclonal and monoclonal antibodies specifically binding to the protein according to the invention and inhibiting or inducing the polymerization of said protein, and polymerization-inhibiting or -inducing proteins, peptides, peptidomimetics and organic molecule-ligands
10 derived from the amino-acid sequence of the protein according to the invention.

The polyclonal and monoclonal antibodies of the invention can be produced by methods known in the art. These methods include the immunological method described by Kohler and Milstein in Nature 256, 495-497 (1975) and Campbell in
15 "Monoclonal Antibody Technology, The Production and Characterization of Rodent and Human Hybridomas" in Burdon et al., Eds., Laboratory Techniques in Biochemistry and Molecular Biology, Volume 13, Elsevier Science Publishers, Amsterdam (1985) as well as by the recombinant DNA method described by Huse et al. in Science 246, 1275-1281 (1989).

20 The antibodies may be prepared in any mammal, including mice, rats, rabbits, goats and humans. The antibody may be a member of one of the following immunoglobulin classes; IgG, IgM, IgA, IgD, or IgE, and the subclasses thereof, and preferably is an IgG antibody.

25 The seventh aspect of the invention is directed to a diagnostic kit comprising as a diagnostic reagent an antibody according to the invention or a modifier according to the invention. The actual diagnostic method which is going to be used will determine possible additional components in the kit, and the kit will preferably be
30 accompanied by instructions for use. An example of a widely used immunological diagnostic method is enzyme linked immunosorbent assay (ELISA), and this has been used in the experimental part of this specification.

35 The eighth aspect of the invention is directed to a useful application of the modifier of the invention, namely a vaccine adjuvant comprising a modifier according to the present invention.

The ninth aspect of the invention is directed to another useful and desirable application of the modifier of the invention, namely a medicament comprising as an active ingredient a modifier according to the present invention.

5

Examples of various applications of the modifiers of the invention are

- leukocyte infiltration
- tumor cell metastasis
- angiogenesis
- 10 - endothelial permeability
- detection of early endothelial cell damage
- adjuvants of oral vaccines, and
- making gut junctions more permeable to antigens, thus indicating use as a
- medicament for the therapeutic or prophylactic treatment of
- 15 acute and chronic inflammatory diseases, organ transplantation, myocardial ischemia, atherosclerosis, cancer, diabetic retinopathy, psoriasis, reumathoid arthritis, intestinal infection.

20

The tenth aspect of the invention is directed to transgenic animals or cells overexpressing or lacking a protein according to the present invention.

25

Transgenic animals carrying null mutation of JAM created by standard techniques [Hogan et. al., Manipulating the mouse embryo: A laboratory manual. Cold Spring Harbor Laboratory Press N.Y. (1994)] will be used as *in vivo* models for screening replacing, activating molecules for JAM and for providing the therapeutic potential of JAM in genetherapy in medicine.

30

JAM-overexpressing animals (e.g. using promoters selected from NSE, Thy 1, PDGFB, VE cadherin, Willebrand factor, and transmodulin) will be used for screening *in vivo* for the therapeutic use of modifiers of JAM polymerization in medicine.

Transgenic cells are used for *in vitro* testing purposes.

35

Having now generally described this invention, the same will become better understood by reference to the specific examples, which are included herein for

- 15 -

purpose of illustration only and are not intended to be limiting unless otherwise specified.

Example 1

5

Generation of mAbs with JAM-neutralizing activity

Antibodies binding specifically to JAM were produced in the laboratory by standard hybridoma techniques as described in Martin-Padura et al., J. Biol. Chem. 269, 6124-6132 (1994). Briefly, Lewis rat was immunized with a murine endothelial cell line (H5V) [Garlanda et al., Proc. Natl. Acad. Sci. USA 91,7291-7295 (1994)]. Hybridomas were produced by fusion of immunized rat splenocytes with Sp2/0 cell line from ATCC (Maryland, USA). Hybridoma supernatants were screened by standard enzyme-linked immunoassay (ELISA) for binding to H5V. Positive hybridoma were then characterized by their ability to stain endothelial cell-cell contacts by immunofluorescence microscopy which technique is disclosed below.

In order to select neutralizing mAbs, mAbs were screened on transmigration of leukocytes through the endothelial monolayers (see below). Mabs BV11 and BV12 were selected after the first screening, and the corresponding hybridomas were serially cloned twice by the method of limiting dilutions. MAb isotypes were determined using a rat isotyping kit (Sigma). Ascites were produced by a standard technique [Martin-Padura et al., supra]. Briefly, Nu/Nu (CD1) BR mice were primed with intraperitoneal injections of 0.5 ml of pristane 6 days before intraperitoneal injection of 10×10^6 hybridoma cells. Ascites were collected after 2-3 weeks. MAb BV11 was purified from ascites by binding to immobilized protein G (Pharmacia), as described by Martin -Padura et al., supra.

30

Example 2

Localization of JAM at tight junctions

Immunofluorescence microscopy

Cells were seeded on glass coverslips and grown to confluence in Medium 199 containing 20 % newborn calf serum before immunofluorescence staining. For some cell types, glass coverslips were coated with human plasma fibronectin (7µg /ml).

Cells were fixed with MeOH for 4 min and processed for indirect immunofluorescence microscopy as previously described in detail by Lampugnani et al., J. Cell. Biol. 118, 1511-1522 (1992). Briefly, incubation with the primary antibody (mAb BV11 or mAb BV 12) was followed by rhodamine-conjugated secondary antibody (Dakopatts) in the presence of fluorescein-labelled phalloidin (1 µg/ml) with several washes with 0.1% BSA in PBS between the various steps. Coverslips were then mounted in Mowiol 4-88 (Calbiochem). A Zeiss Axiophot microscope was used for observation and image recording on Kodak TMax P3200 films.

Confocal laser-scanning immunofluorescence microscopy was done on a Zeiss LSM 410 UV (Carl Zeiss). For simultaneous double-label fluorescence, an Argon ion laser operating at 488 nm and a Helium-Neon laser operating at 543 nm were used together with a band-pass filter combination of 510-525 and 590-610 for visualization of FICT and rhodamine fluorescence, respectively. RGB images were taken in high resolution mode using 1.024 X 1.024 image points (pixels) and 2s scan times. Regularly noise levels were reduced by several line averagings of the scans. Projection images were created from 0.8 µm optical sections of tissue preparation or cell layers. To verify the distribution of JAM and cingulin, the individual images were separated electronically by a 20 pixel off-set along the abscissa.

JAM distributes selectively at cell-cell contacts in endothelial and epithelial cells. Distribution corresponds to other molecules located at tight junctions such as ZO-1 or cingulin. At confocal electron microscopy JAM localizes at tight junction while it is not found in other regions of cell-cell contacts such as adherence junctions.

Example 3

JAM inhibits leukocyte transmigration

A. *in vitro* assay in transwell units

2x10⁵ endothelial cells were seeded on human plasma fibronectin (7 µg/ml, Sigma) precoated polycarbonate membrane of Transwell units (24 mm diameter; 8.0 µm pore size) and cultured for 4 to 5 days to confluency. Cultured medium from both upper and lower chambers were replaced with fresh medium and in some experiments mAbs were added to endothelial cell monolayers for 30 min and then allowed to stay during the transmigration assay. Monocytes were obtained from the

peripheral blood of normal healthy donors as described by Colotta et al., J. Immunol. 132, 936 (1984). Briefly, monocytes (approximately 92% pure) were obtained from Ficoll-Hypaque separated mononuclear cells by centrifugation on a discontinuous (46%) gradient of isosmotic (285 mOsmol) Percoll (Pharmacia).

5 Polymorphonuclear cells were isolated by dextran sedimentation followed by Lymphoprep gradient and hypotonic lysis of erythrocytes, as previously described by Del Maschio et al., Br. J. Haematol. 72, 329-335 (1989). Cells to be used in suspension were resuspended at 10^7 cells/ml in complete medium and labeled by incubation with 100 mCi ^{51}Cr for 1 h at room temperature. Cells were then washed
10 extensively and resuspended at 1.8×10^6 cells/ml in complete medium. An aliquot (1.5 ml) of radiolabelled cells was then added to each well and incubated for 60 min at 37°C . Non-adherent cells were then removed by washing gently with PBS plus 2% FCS from the upper chamber (non-adherent fraction). Transmigrated cells were collected from the lower chamber medium and removed by scraping with cotton
15 buds on the opposite face of the filter. These two fractions were pooled (migrated fraction). The intact EC monolayer together with the adherent leukocytes were collected by cutting the polycarbonate membrane (adherent fraction). Radioactivity of the three fractions was measured in a counter (Beckman).

20 The results are presented in Tables 1, 2 and 3 below.

Table 1. Spontaneous monocyte transmigration *in vitro* through an endothelial monolayer in the presence of different monoclonal antibodies.

25	Treatment	cell number
	Control	437713 ± 14351
	mAb BV11	$190346 \pm 23926^{**}$
	Irrelevant IgG2b	403027 ± 16214
30	mAb BV12	381903 ± 9213
	mAb to CD31	415150 ± 12213

mAb BV11 and mAb BV12 are both antibodies of the invention.

mAb to CD31 is disclosed by Vecchi, A. et. al., Eur. J. Cell Biol. 63, 247-254 (1994)

Antibodies were used as hybridoma supernatants at 1:2 dilution added to the upper chamber. Values are means \pm SEM of four experiments./ ** $p < 0.01$ by analysis of various and Duncan's test. mAb BV11: monoclonal antibody binding to and neutralizing JAM; mAb BV12: monoclonal antibody binding to but not neutralizing JAM.

Table 2. Effect of mAb BV11 on MCP-1-induced monocyte transmigration through an endothelial monolayer.

Treatment	none	MCP-1
Control	323000 \pm 38400	825767 \pm 14351
mAb BV11	172833 \pm 38933**	488967 \pm 13926**
Irrelevant IgG2b	366100 \pm 38400	852250 \pm 16214

MCP-1 at 100 ng/ml was added to the lower compartment 5 min before monocyte seeding. Antibodies were used as hybridoma supernatants at 1:2 dilution added to the upper chamber. Values are means \pm SEM of two experiments. ** $p < 0.01$ by analysis of various and Duncan's test. mAb BV11: monoclonal antibody neutralizing JAM.

Table 3. Effect of mAb BV11 on polymorphonuclear cell (PMN) migration through an endothelial monolayer.

Treatment	none	fMLP (10 nM)
Control	25566 \pm 3486	69400 \pm 2275
mAb BV11	24852 \pm 3854	24852 \pm 1916**
Irrelevant IgG2b	26890 \pm 3890	68890 \pm 1934

Chemotaxis was induced by addition of fMLP (500 nM) to the lower compartment of the Transwell unit. Antibodies were used as hybridoma supernatants at 1:2 dilution added to the upper chamber. Values are means \pm SEM of two experiments. ** $p <$

0.01 by analysis of variance and Duncan's test. mAb BV11: monoclonal antibody neutralizing JAM.

In conclusion, as reported in Tables 1, 2 and 3, addition of monoclonal antibody BV11 specifically binding to JAM resulted in the inhibition of both monocyte and polymorphonuclear cell transmigration. The antibody did not significantly alter the number of cells which remained adherent to the filter.

B. *in vivo* assay: measurement of leukocyte recruitment in the air pouch model

Mice were anesthetized with ether and 5 ml of sterile air were injected under the skin in the back (day 0). After three days pouches were reinjected with 3 ml of sterile air. On day 4, animals received intravenous injection of 200 µg of monoclonal antibody BV11 binding specifically to JAM or the same dose of nonimmune rat IgG (Sigma). On day 6; 1 ml of 1% carrageenan in saline was injected into the pouch. At different times after carrageenan the animals were anesthetized and the pouches were washed with 1 ml of saline. The lavage fluid was immediately cooled on ice and the volume was recorded. Then 50 µl were used for cell count after staining with erythrosin.

The results are presented in Table 4 below.

Table 4. Effect of mAb BV11 on neutrophil recruitment *in vivo*

Treatment	cell number (x 10 ⁶)
Control	5.769 ± 0.932
mAb BV11	3.629 ± 0.217*

Leukocyte recruitment was induced by injection of carrageenan in sterile saline (1 ml) into six day-old pouches. 200 µg of purified mAb BV11 (mAb binding to JAM) or rat non-immune-IgG (control) were injected intravenously in 200 µl 12 hours before carrageenan treatment. Animals were killed 48 hours after the treatment. Data are mean ± SD of at least seven animals in two experiments. * p < 0.002 according to Student's t test.

In conclusion, as reported in Table 4, the number of polymorphonuclear cells found in the air pouch after carrageenan injection was significantly reduced in the mice treated with the monoclonal antibody BV11 specifically binding to JAM in respect to mice IgG.

Table 5. Effect of mAb BV11 on paracellular permeability *in vivo*

Treatment	Control	mAb BV11
Exudate (ml)	1.49 \pm 0.125	1.28 \pm 0.217*

Measurement of permeability in the air pouch model was evaluated as collected exudate volume. Plasma exudation was induced by carrageenan in sterile saline (1 ml) in six day-old pouches. 200 μ g of purified mAb BV11 (mAb binding to JAM) or rat non-immune-IgG (control) were injected intravenously in 200 μ l 12 hours before carrageenan treatment. Animals were killed 48 hours after the treatment. Data are mean \pm SD of at least 8 animals in two experiments. * $p < 0.049$ according to Student's t test.

Example 4

Inhibition of paracellular permeability by JAM

A. Constructs and Transfection

Constructs preparation and transfection procedures were performed according to Breviario et al., Arterioscler. Throm. Vasc. Biol. 15, 1229-1239 (1995). JAM cDNA was isolated through expression cloning. The cDNA expression library was constructed from a murine brain EC line (bEnd.3) as previously described (Fawcett et al., Nature 360, 481 [1992]; Seed, Nature 329, 840 [1987]; Seed and Aruffo, Proc. Natl. Acad. Sci. U.S.A. 84, 3365 [1987]; Simmons et al. Nature 331, 624 [1988]). The cDNA library was oligo-dT primed bEnd.3 polyA + RNA cloned into pCDM8 (Nature 329, 840-842 [1987]). Plasmid pCDM8 was cut with HindIII and NotI enzymes and the insert was blunted and subcloned into the SmaI restriction site of pECE eucaryotic expression vector (Rutter et al., Cell 45, 721-732 [1986]) to give the pECE-JAM

construct. The construct was then checked for correct orientation by sequence analysis using the dideoxynucleotide chain termination method ("Molecular Cloning", Second Edition, Cold Spring Harbor Laboratory Press (1987) and Ausubel et al. (Eds) "Current Protocols in Molecular Biology, "Green Publishing Associates / Wiley-Interscience, New York (1990)). CHO cells were plated at $3-4 \times 10^6$ cells per 100 mm petri dish in DMEM with 10% FCS. 24 h after seeding cells were transfected by calcium phosphate precipitation method with 20 μ g of pECE-JAM and 2 μ g of plasmid pSV2 neo (Rutter et al., supra). After 24 h, the DNA-containing medium was replaced by fresh DMEM with 10% FCS and maintained for further 48 h. Then cells were detached and plated at 1×10^6 per 100 mm petri dish and cultured in selective medium with 600 μ g/ml G418 (Geneticin, GIBCO). Resistant colonies were isolated and tested for BV11 antigen expression by immunofluorescence staining and immunoprecipitation analysis. Positive cells were cloned by limiting dilution and expanded for further studies.

B. Measurement of dextran passage in Transwell units

Procedure to measuring permeability across the cell monolayer in Transwell units is extensively described in Breviario et al., supra. Briefly, JAM transfectant or endothelial cells were seeded at 1.5×10^4 per 6.5 mm in Transwell units (polycarbonate filter, 0.4 mm pore, Costar) and cultured to confluency for 5 days. Then, culture medium was replaced with serum-free medium and fluorescein isothiocyanate-dextran (1 mg/ml, Sigma) was added to the upper chamber. At different times, 100 μ l from the lower compartment were withdrawn and assayed by fluorimeter (excitation wavelength set at 492 nm and emission at 520 nm).

The results are presented in Table 6.

Table 6. Effect of JAM transfection on paracellular permeability.

Transfectant cells	% Permeability
Control	100.0 ± 2.5
JAM	46.5 ± 2.0
JAM + EGTA 5mM	110.0 ± 4.4
JAM + Cyt D	91.0 ± 6.5

- 22 -

Values are means \pm SEM of three independent experiments/ ** $p < 0.01$ by analysis of various and Duncan's test.

Transfectants were seeded on Transwell filters, dextran was added to the upper compartment and its passage to the lower compartment was evaluated at 2 hours. Permeability in JAM transfectants was increased by addition of EGTA and cytochalasin D indicating that the activity is Ca^{++} dependent and requires an intact actin cytoskeleton.

In conclusion, as reported in Table 6, JAM transfection significantly reduced the passage of dextran through intercellular junctions. As reference the Table also reports the effect of permeability increasing agents such as EGTA and cytochalasin D. This also shows that JAM needs Ca^{++} and an intact actin cytoskeleton to exert its effect.

Example 5

Use of mAb BV11 to detect JAM in ELISA assay

ELISA sandwich

An ELISA standard protocol was followed [Peri et al., J. Immunol. Meth. 174, 249-257, (1994)]. Briefly, 96 well ELISA plates (Falcon) were coated with 50 μ l/well of rabbit anti-JAM serum diluted 1/3000 in 15 mM carbonate buffer, pH 9.6 and incubated overnight at 4°C. After incubation, plates were washed three times with PBS + 0.05% Tween 20 (washing buffer). Non-specific binding was blocked with 5% dry milk in washing buffer for 2h at room temperature. After wash, JAM-containing samples were added for 2h at 37°C. Then, plates were washed and incubated with mAb BV11 for 1h at 37°C. Peroxidase conjugated anti-rat IgG (diluted 1:2000, Sigma) was incubated for 1h at RT and then 100 μ l chromogen substrate was added.

Adsorbance values were read at 405 nm.

The results are presented in Table 7.

Table 7. Detection of JAM (O.D.) on different cells in ELISA

Treatment	endothelial cells	3T3 fibroblasts	Mel(hemopoietic line)
Control	150 \pm 10	136 \pm 21	166 \pm 14
mAb BV 11	920 \pm 7 **	142 \pm 16	169 \pm 19
non-immune serum	167 \pm 5	148 \pm 9	179 \pm 9

- 10 Control: only secondary antibody was added. Rabbit anti-JAM serum or non-immune rabbit serum were used at dilution 1/3000. Adsorbance values are means \pm SEM of four replicates/ ** $p < 0.01$ by analysis of various and Duncan's test.

- 15 In conclusion, in ELISA the mAb BV11 was able to detect JAM protein in solubilized endothelial cells and JAM transfectant cells while it gave negative values using the extracts of cells which do not express JAM such as hemopoietic precursor cell lines and 3T3 fibroblasts.

Example 6

20

Expression of soluble JAM

- 25 An extracellular JAM fragment was cloned by PCR [Saiki et al., Science 239, 487 (1988)] from full length JAM cDNA introducing a Kpn1 restriction site upstream the start codon and a stop codon at position 775 just in front a HindIII restriction site. The amplified DNA was cut by the restriction enzymes Kpn1 and HindIII and the resulting DNA was ligated into the cloning site of the baculovirus expression vector pFASTBAC1 (Gibco BRL). The vector was transformed into DH10Bac cells (Gibco BRL), the transformants were plated and stained with x-Gal according to the
- 30 recommendation of the manufacturer. After selection of a recombinant vector, the DNA was transfected into Sf9 cells. Soluble JAM was detected in the cell culture medium seven days after transfection with the vector or three days after infection with the recombinant baculovirus.

- 35 Purified soluble JAM aggregates by itself depending on the solvent conditions. Inhibitors of the JAM self aggregation can be identified by physical methods (light

- 24 -

scattering, ultracentrifugation, gelpermeation chromatography, BiaCore etc.) or, as described below, by a two-sided sandwich type immunoassay using the monoclonal antibodies of this invention (mab BV11 and mab BV12). Briefly, Immunoplates (Nunc Maxisorb) are coated overnight with 100 µl/well of a solution of mab BV12 (10 µg/ml) in 0.1 M sodium bicarbonate buffer. The wells are blocked by addition of blocking buffer (1% bovine serum albumin in Tris-buffered saline, 0.05% Tween 20 pH 7.5; 100 µl/well). After three hours the wells are washed and the sample of soluble JAM is added together with the aggregation inhibitor at suitable dilution. After incubation overnight in the cold the sample is removed, the wells are washed and an antibody-enzyme conjugate is added at suitable concentration diluted with blocking buffer. The antibody-enzyme conjugate may be prepared by coupling mab BV12 to activated horseradish peroxidase according to Nakane and Kawaoi (J. Histochem. Cytochem. 22, 1084-1091 [1975]). The plate is washed and incubated with a colorimetric enzyme substrate, e.g., tetramethyl benzidine and hydrogenperoxide. Inhibitors of JAM self aggregation are recognized by reduction of the bound peroxidase activity. A similar assay using mab BV11 or BV12 for coating the plate can be used for measuring soluble JAM as diagnostic marker of murine endothelial cell damage / proliferation.

CLAIMS

1. Protein in glycosylated or unglycosylated form comprising an amino-acid
sequence selected from the sequence SEQ ID NO:1 and homologous sequences
5 having at least 72% homology thereto.
2. Protein according to claim 1, wherein said sequence is SEQ ID NO:2
3. DNA sequence coding for a protein as claimed in claim 1 or 2.
10
4. DNA sequence according to claim 3 selected from the group consisting of SEQ
ID NO:3 and SEQ ID NO:4
5. Gene coding for a protein as claimed in claim 1 or a peptide derived therefrom.
15
6. Gene according to claim 5 selected from the group consisting of SEQ ID NO:5
and SEQ ID NO:6.
7. Vector comprising a DNA sequence as claimed in claim 4 or a gene as claimed
20 in claim 5 or 6.
8. Organisms transformed with a vector as claimed in claim 7.
9. Recombinant protein or peptide expressed by a gene or a fragment of the gene
25 according to claim 5 or 6.
10. Antibody binding specifically to a protein according to claim 1 or a part of the
protein.
- 30 11. Modifier of the polymerization of a transmembrane protein defined in claim 1.
12. Modifier according to claim 11 selected from the group consisting of antibodies
specifically binding to the protein defined in claim 1 and inhibiting or inducing the
polymerization of the protein, and polymerization-inhibiting or -inducing proteins,
35 peptides, peptidomimetics and organic molecule-ligands derived from the amino-
acid sequence of the protein defined in claim 1.

- 34 -

()

13. Diagnostic kit comprising as a diagnostic reagent an antibody according to claim 10 or a modifier according to claim 11 or 12.

5 14. Vaccine adjuvant comprising a modifier according to claim 11 or 12.

15. Medicament comprising as an active ingredient a modifier according to claim 11 or 12.

10 16. The use of a protein according to claim 1 for identifying and isolating modifiers of its polymerization.

17. The use of a modifier according to claim 11 or 12 for the preparation of medicaments.

15

18. A method for producing a protein as claimed in claim 1 or 2, comprising cultivating an organism as claimed in claim 8 in a suitable medium and optionally isolating said protein.

20 19. Proteins as claimed in claim 1 or 2 prepared by the method of claim 18.

20. A modifier according to claim 11 or 12 as active ingredient in medicaments.

25 21. The invention substantially as hereinbefore described, especially with reference to the examples.

INTERNATIONAL SEARCH REPORT

International Application No

PCT/EP 97/06723

A. CLASSIFICATION OF SUBJECT MATTER

IPC 6 C12N15/12 C07K14/705 C07K16/28 G01N33/53 G01N33/566
A61K39/395 A61K38/17 A01K67/027

According to International Patent Classification (IPC) or to both national classification and IPC

B. FIELDS SEARCHED

Minimum documentation searched (classification system followed by classification symbols)

IPC 6 C12N C07K G01N A61K A01K

Documentation searched other than minimum documentation to the extent that such documents are included in the fields searched

Electronic data base consulted during the international search (name of data base and, where practical, search terms used)

C. DOCUMENTS CONSIDERED TO BE RELEVANT

Category *	Citation of document, with indication, where appropriate, of the relevant passages	Relevant to claim No.
X	NAIK U.P. ET AL.: "Mechanisms of platelet activation by a stimulatory antibody: cross linking of a novel platelet receptor for monoclonal antibody F11 with the Fc-gammaRII receptor." BIOCHEMICAL JOURNAL, vol. 310, 1995, pages 155-162, XP002060366 see table 2	1-21
X	WANG F. ET AL.: "Stimulatory antibody-induced activation and selective translocation of protein kinase C isoenzymes in human platelets." BIOCHEMICAL JOURNAL, vol. 311, no. 2, 1995, pages 401-406, XP002060055 see the whole document	1-21

☒ Further documents are listed in the continuation of box C.

☒ Patent family members are listed in annex.

* Special categories of cited documents:

- "A" document defining the general state of the art which is not considered to be of particular relevance
- "E" earlier document but published on or after the international filing date
- "L" document which may throw doubts on priority claim(s) or which is cited to establish the publication date of another citation or other special reason (as specified)
- "O" document referring to an oral disclosure, use, exhibition or other means
- "P" document published prior to the international filing date but later than the priority date claimed

"T" later document published after the international filing date or priority date and not in conflict with the application but cited to understand the principle or theory underlying the invention

"X" document of particular relevance; the claimed invention cannot be considered novel or cannot be considered to involve an inventive step when the document is taken alone

"Y" document of particular relevance; the claimed invention cannot be considered to involve an inventive step when the document is combined with one or more other such documents, such combination being obvious to a person skilled in the art.

"Z" document member of the same patent family
